

Total Δ SLR (relative to 2020)

Hybrid Hawkins-Sutton variance decomposition of total Δ SLR. Internal variability (FaIR seeds) and BRICK posterior are model-free estimates from within-cell variance across augmentation runs (10 seeds × 200 cells; 10 BRICK posts × 10,000 cells). Climate response (FaIR configs) and emissions (RFF-SP) come from Shapley TreeExplainer attribution on cfg + RFF features. AIS tipping nonlinearity = residual variance lost when the target is p99-clipped per year. Unattributed = residual after tipping.
