

Pulse-marginal Δ SLR (per GtCO₂, 2030 pulse)

Group-Sobol Hawkins-Sutton variance decomposition of pulse-marginal Δ SLR (per GtCO₂, 2030 pulse). Matched-seed paired difference cancels internal variability by construction ($V_{\text{internal}} = 0$). Emissions (RFF-SP), climate (FaIR configs), and BRICK posterior are grouped first-order Sobol indices from a HistGB surrogate (Saltelli, importance weighted); interactions = total-minus-first-order. AIS tipping nonlinearity = variance lost when the target is p99-clipped per year. Shares normalized to the surrogate-explained variance; the residual model-unresolved variance is not shown.
