

Total Δ SLR (relative to 2020)

Group-Sobol Hawkins-Sutton variance decomposition of total Δ SLR. Emissions (RFF-SP), climate response (FaIR configs), and BRICK posterior are grouped first-order Sobol indices from a HistGB surrogate (Saltelli pick-and-freeze, importance weighted); interactions = aggregate total-minus-first-order (climate x BRICK, emissions x BRICK). Internal variability (FaIR seeds) is the model-free seed-augmentation estimate. AIS tipping nonlinearity = variance lost when the target is p99-clipped per year. Shares are normalized to the surrogate-explained variance (OOF $R^2 \approx 0.8 \rightarrow 0.7$ over 2050 $\rightarrow$ 2150); the residual model-unresolved variance is not shown.
